Discussion 1

1. After installing XAMPP application and if you need to save your PHP files on your PC, in what a place can you save it and in what extension for these files?

- We need to save our PHP files in the falling path:
C:\xampp\htdocs.
And with .PHP extension.

2. htdocs is acronyms for what?

- htdocs stands for "HyperTextDocumentS".

3. Suppose your PC is running with Windows operating system, can you install MAMP package on it? Explain your answer.

- yes, you can but XAMPP is the ideal option

4. Give me some examples about some web sites that are built with PHP.

- Spotify, Facebook, Canva, Tumblr, WordPress and more.

5. As you remember, JavaScript is a popular client-side programming language and it has the ability to change the content and style of a web page dynamically. One question you may be asking is, "Why do we need a server-side programming language, too?"

-Its emphasis on running in a client's browser means that JavaScript can't perform the essential role of a server-side back end on its own

And Js appears to require more lines of code to execute the same tasks as PHP.
